Application of Seismic Refraction Tomography to Karst Cavities

Many seismic methods have been applied to karst problems, but few have been successful. Some success has been attained in detecting sink-holes, or other structural features that lie above voids, but it has proven difficult to image or detect cavities with seismic methods. Conventional seis-mic refraction methods (e.g. delay-time or general-

Seismic refraction tomography SRT 2 interpreted. The SRT 2 is parallel to SRT 1, and the scale indicates the alignment. Tomography SRT1 exhibits a surface zone 5–14 m thick that extends along the whole section. It is composed of the natural unconsolidated overburden and the artificial body of the road embankment, with P-wave velocity in the ...

Application of Seismic Tomography and Geotechnical ...

Recently, new interpretation methods have been developed and seismic refraction tomography (SRT) is one of the main techniques to constrain the three-dimensional (3D) distribution of physical properties that affect the seismic wave propagation (Thurber and Ritsema, 2007). It provides the possibility to obtain continuous velocity variations across a grid in the seismic profile.

Application of near-surface seismic refraction tomography ...

In particular, top of rock revealed by an excavation, and pile tip elevations at driving refusal, were compared with refraction test results. From these data it appears that seismic wave tomograms can characterize the soil/rock interface, and that it is possible to predict expected design pile lengths based upon a measured P-wave velocity tomogram. It can be concluded from these site comparisons that geophysical techniques such as seismic refraction tomography can provide important ...

Seismic Refraction - Geometrics : Geometrics

A seismic tomography program is used for the calculation of the travel times and inversion process (Hermann et al., 1982, Kanl?, 2008). Vidale's (1988) algorithm is applied to the calculation of the travel-time field for the given model and the spread system. The calculated travel-time data are referred to as the "measured" travel times throughout the paper in synthetic studies.

Initial velocity model construction of seismic tomography ...

The seismic refraction method requires three components: a controlled shot of seismic energy (source), sensors to receive the energy (geophones), and a central data recorder (seismograph) connected via radio links or cabling. The transmitted energy is recorded at each geophone along the seismic line.

Refraction tomography Unlike conventional refraction methods, seismic refraction tomography (SRT) does not require that the model be broken into continuous layers having constant velocity. Instead, the model is made up of a large number of small constant velocity grid cells or nodes.

The new frontier of seismic tomography will open great perspective not only for modelling the main geometrical features, but also for giving accurate details about the underground geological characteristics. The energy source is represented by an impact on the surface.

Seismic refraction tomography is based on determination of time interval that elapses between an initiation of a seismic waves at a certain shot point and the arrival of refracted waves at one or more seismic detector (Figure 3). Seismic refraction tomography uses a wave's propagation in ground surface which is dependent on the velocity

Application of 2D Resistivity Imaging and Seismic ...

The seismic refraction method utilizes the refraction of seismic waves by rock or soil layers to characterize the subsurface geologic conditions and geologic structure. Seismic refraction is exploited in engineering geology, geotechnical engineering and exploration geophysics.
