Advances in understanding the immunological and molecular basis of autoimmune diseases have made gene therapy a promising approach to treat the affected patients. Gene therapy for autoimmune diseases aims to regulate the levels of proinflammatory cytokines or molecules and the infiltration of lymphocytes to the effected sites through successful delivery and expression of therapeutic genes in appropriate cells.

The first human gene therapy trial for an autoimmune disease started last year.²⁴ Nine patients with RA will be treated by ex vivo retroviral delivery of a cDNA encoding human IL1Ra. Because this is the first human use of gene therapy for a disease that is not considered lethal, the overriding priority has been to establish the safety of gene transfer to diseased joints.

APS-1 is solely caused by mutations in the autoimmune regulator gene (AIRE), making it an attractive candidate for gene therapy. We have already developed a novel gene therapy approach based on adeno-associated virus-mediated AIRE replacement (AAV-AIRE). In a mouse model of APS-1, direct AAV-AIRE injection to the thymus in pre-symptomatic mice led to clearance and protection of all tissues targeted by the immune attack.

There is considerable evidence from animal studies that gene therapies work: examples include the treatment of experimental models of rheumatoid arthritis, multiple sclerosis, diabetes, and lupus. Pre-clinical success in treating animal models of rheumatoid arthritis has led to the first clinical trial of gene therapy for an autoimmune disease.

Immune Gene Therapy for Acute Myeloid Leukaemia. Acute myeloid leukaemia (AML) cells share a common lineage with professional antigen presenting cells (APC), expressing many adhesion and stimulatory molecules, as well as both MHC-I/II molecules and the required machinery for presentation of the leukaemia associated antigens. However, AML cells are poorly immunogenic, in fact with well documented immune suppressive activities, probably because they lack co-stimulatory molecules and express ...

The euglycemia in toxin-induced diabetic mice and new insulin + cells persisted in the autoimmune NOD mice for 4 months prior to reestablishment of autoimmune diabetes. This gene therapy strategy also induced alpha to beta cell conversion in toxin-treated human islets, which restored blood glucose levels in NOD/SCID mice upon transplantation.

Stanford neuroimmunologist Larry Steinman, MD, and his colleagues have demonstrated that gene therapy can be effective without causing a dangerous side effect common to all gene therapy: an autoimmune reaction to the normal (healthy) protein, which the patient with a damaged form of the protein is encountering for the first time.
