Abstract. Recent empirical studies suggest that genes involved in speciation are often sex-linked. We derive a general analytic model of reinforcement to study the effects of sex linkage on reinforcement under three forms of selection against hybrids: one-locus, two-locus, and ecological incompatibilities.

Genes on the X chromosome are referred to as sex-linked, or X-linked, genes. Normally, in the nonsex chromosomes, the genes on both of the pairs of chromosomes are capable of being fully expressed. However, in females, most of the genes on one of the two X chromosomes are turned off through a process called X inactivation (except in the eggs in ...

Genes are packaged in bundles called chromosomes. Humans have 23 pairs of chromosomes, resulting in 46 individual chromosomes. Of those pairs, one pair, the x and y chromosome, determines whether you are male or female, plus some other body characteristics. Females have an XX pair of chromosomes while men have a pair of XY chromosomes.

TRAITS, GENES, AND ALLELES Reinforcement KEY CONCEPT Genes encode proteins that produce a diverse range of traits. A gene is a segment of DNA that tells the cell how to make a particular polypeptide. The location of a gene on a chromosome is called a locus. A gene has the same locus on both chromosomes in a pair of homologous chromosomes.

Genes control the genetic traits, and genes are DNA, which is organized into chromosomes. Both prokaryotes and eukaryotes have chromosomes, although the organization level is different. A gene is a region of DNA segment that controls certain trait of inheritance, while chromosome is the basic inheritance unit in cells.
