In this study, both the blade and the wake aerodynamics of a straight-bladed VAWT are investigated using a three-dimensional computational fluid dynamics (CFD) model. The algebraic wall-modeled large eddy simulation (LES) was used for turbulence modeling.

The solidity ratio refers to the total blade area over the swept area of rotor blades, i.e., $\sigma = Nc/(D)$, where N is the number of blades, c is the chord length, and D is the turbine diameter. McLaren and colleagues conducted a systematic investigation into the aerodynamic loading behavior of blades for a high-solidity three-bladed VAWT in a wind tunnel (McLaren, 2011 , McLaren et al., 2012).

"A dip in performance was observed for cases with rotors very close to each other at low Re . It was hypothesized that the interaction of rotor blades with the tip vortex cores of the neighboring rotor blades at small axis shifts could be a reason for the effect on efficiency.

For Horizontal Axis Wind Turbine (HAWT), the aerodynamic performance of the blade will become different when the geometry of the blade is bent backward in the rotor plane, which is usually called backward swept blade. In this paper the aerodynamic performance of backward swept-blade rotor will be analyzed by Free Wake Lifting Line Model and the corresponding wake vortexes are discussed. In order to make it possible to apply lifting line method, a proper 3D effect modification model is needed ...
