The structure is a flat-bottomed, reinforced concrete tank with a 20-ft water depth. The allowable leakage rate is 0.1 percent of the water volume in 24 h. To determine the duration of the test: 0.5 in./ (0.001 in./in./d x 20 ft x 12 in./ft) = 2.08 days Measurements are taken at 24-h intervals. Therefore, the test duration should be a minimum of three

Testing Reinforced Concrete Structures for Watertightness

As discussed in Load Testing of Concrete Structures – Part 1 (STRUCTURE ® magazine, April 2014), load testing can be used to determine the ability of a structure to carry additional loads, to establish the safety of structures, to validate strengthening, to gain knowledge on the behavior of a structure, and to supplement, validate or refine analytical work models. Part 1 discussed different aspects of in-situ load testing including the load test program, methods of load application and ...

This paper presents the results of shaking table tests on a tri-axial 1/2.5-scale 3-story self-centering reinforced concrete frame structure. Based on the results of this study, the following conclusions can be drawn: (1) The tri-axial self-centering RC frame structure had outstanding seismic performance even under extreme earthquakes.

Specialist Engineers for the Inspection & Testing of Concrete Structures. Reinforced concrete structures suffer from a variety of problems which may require urgent repair in order to prevent further deterioration. These range from initial construction defects and poor detailing to the effects of our modern environment over time. As many concrete structures are of significant height, the spalling of cover concrete presents a real and present danger for owners and occupiers.

Large scale reinforced concrete (RC) shear wall structures have been tested by many researchers, including, e.g., Yabana et al. , Bachmann , , Lu and Wu , Combesure and Sollogoub , Panagiotou et al. , Ghorbanirenani et al. and Richard et al. , , among others. Most of these shake table tests were conducted for the verification or checking of global performance of structures.

Testing and modeling the structural behavior of reinforced concrete structures is a challenging task that has attracted the attention of researchers for more than 100 years. In the past, models to predict the strength of RC members were mainly formulated as simple empirical expressions derived from results of ordinary standard tests by means of statistical analysis.
